# Explicit Bounds for the Burgess Bound for Character Sums 

Enrique Treviño

Maine/Québec Number Theory Conference, 2009

## Short Character Sums

## Let $\chi$ be a non-principal character of modulus $p$.

$$
S_{\chi}(N)=\sum_{M<n \leq N+M} \chi(n)
$$

## Polya-Vinongradov

- Polya-Vinogradov $S_{\chi}(N) \ll \sqrt{p} \log p$
- Constant made explicit and improved by people over time.
- Constant made explicit with a small constant and secondary term (Pomerance):

$$
S_{\chi}(N) \leq \frac{1}{3 \log 3} \sqrt{p} \log p+2 \sqrt{p}
$$

## Burgess

In the 60s, Burgess came out with the following:

## Theorem (D. Burgess)

Let $\chi$ be a primitive character of conductor $q>1$. Then

$$
S_{\chi}(N)=\sum_{M<n \leq M+N} \chi(n) \ll N^{1-\frac{1}{r}} q^{\frac{r+1}{4 r^{2}}+\epsilon}
$$

for $r=2,3$ and for any $r \geq 1$ if $q$ is cubrefree, the implied constant depending only on $\epsilon$ and $r$.

## Applications

- Improving upperbound for least quadratic non-reside $(\bmod p)$
- Calculating $L(1, \chi)$

## Theorem (Iwaniec-Kowalski-Friedlander)

Let $\chi$ be a Dirichlet character mod $p$. Then for $r \geq 2$

$$
\left|S_{\chi}(N)\right| \leq 30 \cdot N^{1-\frac{1}{r}} p^{\frac{r+1}{4 r^{2}}}(\log p)^{\frac{1}{r}}
$$

## Improvement

## Theorem (ET)

Let $\chi$ be a Dirichlet character mod $p$. Then for $2 \leq r \leq 87$ and $p \geq 10^{7}$.

$$
\left|S_{\chi}(N)\right| \leq 3 \cdot N^{1-\frac{1}{r}} p^{\frac{r+1}{4 r^{2}}}(\log p)^{\frac{1}{r}}
$$

Note, the constant gets better for larger $r$, for example for $r=3,4,5,6$ the constant is $2.376,2.085,1.909,1.792$ respectively.

## Proof

Idea 1: Shift, take average and use induction

$$
\begin{aligned}
& S_{\chi}(N)=\sum_{M<n \leq M+N} \chi(n+a b)+\sum_{M<n \leq M+a b} \chi(n)-\sum_{M+N<n \leq M+N+a b} \chi(n) \\
& 1 \leq a \leq A, 1 \leq b \leq B .
\end{aligned}
$$

Take average as $a$ and $b$ move around their options.

## Proof Cont.

$$
V=\sum_{a, b} \sum_{M<n \leq M+N} \chi(n+a b)
$$

Since $\chi(n+a b)=\chi(a) \chi(\bar{a} n+b)$, we have that

$$
V=\sum_{x(\bmod p)} v(x)\left|\sum_{1 \leq b \leq B} \chi(x+b)\right|
$$

where $v(x)$ is the number of ways of writing $x$ as $\bar{a} n$ where a and $n$ are in the proper ranges.

## Proof Cont.

Idea 2: Holder's Inequality

$$
\text { - Let } V_{1}=\sum_{x(\bmod p)} v(x)=A N
$$

- Let $V_{2}=\sum_{x(\bmod p)} v^{2}(x)$
- Let $W=\sum_{x(\bmod p)}\left|\sum_{1 \leq b \leq B} \chi(x+b)\right|^{2 r}$.

By Holder's Inequality we get

$$
V \leq V_{1}^{1-\frac{1}{r}} V_{2}^{\frac{1}{2 r}} W^{\frac{1}{2 r}}
$$

## Proof Cont.

## Lemma

For $A \geq 40$ and $A \leq \frac{N}{15}$,

$$
V_{2}=\sum_{x(\bmod p)} v^{2}(x) \leq 2 A N\left(\frac{A N}{p}+\log (2 A)\right)
$$

$V_{2}$ is the number of quadruples $\left(a_{1}, a_{2}, n_{1}, n_{2}\right)$ with $1 \leq a_{1}, a_{2} \leq A$ and $M<n_{1}, n_{2} \leq M+N$ such that $a_{1} n_{2} \equiv a_{2} n_{1}$ $(\bmod p)$.

$$
V_{2} \leq A N+\sum_{a_{1}<a_{2}}\left(\frac{\left(a_{1}+a_{2}\right) N}{\operatorname{gcd}\left(a_{1}, a_{2}\right) p}+1\right)\left(\frac{\operatorname{gcd}\left(a_{1}, a_{2}\right) N}{\max \left\{a_{1}, a_{2}\right\}}+1\right)
$$

## Ending Proof

- To bound $W$ we use Weil's bound.
- Optimize the choices of $A$ and $B$.
- Combine the lemmas with the induction hypothesis and figure out the constant.

## Quadratic Case (Booker)

## Theorem (Booker)

Let $p>10^{20}$ be a prime number $\equiv 1(\bmod 4), r \in\{2, \ldots, 15\}$ and $0<M, N \leq 2 \sqrt{p}$. Let $\chi$ be a quadratic character $(\bmod p)$. Then

$$
\left|\sum_{M \leq n<M+N} \chi(n)\right| \leq \alpha(r) p^{\frac{r+1}{4 r^{2}}}(\log p+\beta(r))^{\frac{1}{2 r}} N^{1-\frac{1}{r}}
$$

where $\alpha(r), \beta(r)$ are given by

| $r$ | $\alpha(r)$ | $\beta(r)$ | $r$ | $\alpha(r)$ | $\beta(r)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | 1.8221 | 8.9077 | 9 | 1.4548 | 0.0085 |
| 3 | 1.8000 | 5.3948 | 10 | 1.4231 | -0.4106 |
| 4 | 1.7263 | 3.6658 | 11 | 1.3958 | -0.7848 |
| 5 | 1.6526 | 2.5405 | 12 | 1.3721 | -1.1232 |
| 6 | 1.5892 | 1.7059 | 13 | 1.3512 | -1.4323 |
| 7 | 1.5363 | 1.0405 | 14 | 1.3328 | -1.7169 |
| 8 | 1.4921 | 0.4856 | 15 | 1.3164 | -1.9808 |

## Improving Booker

For $r \geq 3$ we can do the following:

$$
c_{r} N^{1-\frac{1}{r}} p^{\frac{r+1}{4 r^{2}}} \log (p)^{\frac{1}{2 r}}<c_{2} N^{\frac{1}{2}} p^{\frac{3}{16}} \log (p)^{\frac{1}{2}}
$$

Then

$$
N \leq\left(\frac{c_{2}}{c_{r}}\right)^{\frac{2 r}{r-2}} p^{\frac{3 r+2}{8 r}}(\log (p))^{\frac{r-1}{r-2}}
$$

Therefore we have $N<\sqrt{p}$. Hence the range Booker gets can be extended for $r \geq 3$.

## Improving the Log Factor in the General Case

The same trick gets us to improve my theorem to:

## Theorem (ET)

Let $\chi$ be a Dirichlet character mod $p$. Then for $r \geq 3, r \leq 74$ and $p \geq 10^{7}$.

$$
\left|S_{\chi}(N)\right| \leq 2.4 \cdot N^{1-\frac{1}{r}} p^{\frac{r+1}{4 r^{2}}}(\log p)^{\frac{1}{2 r}}
$$

## Acknowledgements

- My advisor Carl Pomerance for suggesting the problem and guidance.
- NSF, University of Maine for the financial support.
- Burgess, Iwaniec, Friedlander, Kowalski, Booker, Montgomery, Vaughan and Granville for their work on character sums.
